Abstract

System of double quantum dots under influence of DC-magnetic field has been discussed and analyzed. The tunneling current is calculated as a function of DC-magnetic field using the equation of motion for the state occupation probabilities, the results evidence that the resonance energy is dominant factor affected in the current.

Keywords: quantum dots, polarization, tunneling rate, occupation probability.

*It’s a part of M.Sc. thesis submitted by the first author.
1. Introduction

The name “dot or island” is often called artificial atom because of it’s quantum properties\(^{(1)}\), and their electronic characteristics are closely related to the size and shape of the individual crystal\(^{(2)}\). Two quantum dots can be coupled to form an artificial molecule and the bond of the artificial molecule, depends on the strength of the inter dot coupling which can form ionic like (weak tunnel coupling) or covalent like bonds (strong tunnel coupling).

The quantum dots have very sharp density of state because of their nano-size, they have excellent transport and optical properties, so their transport process gives many interesting phenomena seen in the electronic device like coulomb blockade\(^{(3)}\), spin blockade\(^{(4)}\), and more applications like spintronic\(^{(5)}\), and quantum information\(^{(6)}\).

Spin degree of freedom of electrons in quantum dots has a great potential as a carrier of classical information\(^{(5)}\) and quantum information, spin quantum bits\(^{(6)}\).

The study of current in quantum dots has attracted much attention in the recent decades\(^{(7-12)}\).

Following the work of Emary\(^{(13)}\), we study the current between the double dots system connected to a non magnetic leads as shown in the figure(1).

![Schematic diagram of a double quantum dots connected to the two leads under the influence of DC magnetic field in the Z-direction.](image)

**Figure 1:** Schematic diagram of a double quantum dots connected to the two leads under the influence of DC magnetic field in the Z-direction.
In Fig(1), consider the left dot has an s-type orbital and the right dot has three orbitals, also consider a DC magnetic field applied on the dots in the Z-direction, and the dots are from different material, so they have different g-factors.

2. System Hamiltonian

The system can be described by the Hamiltonian:

$$\hat{H} = \hat{H}_L + \hat{H}_R + \hat{H}_{LR} + \hat{H}_T + \hat{H}_{leads}$$  \hspace{1cm} (1)

Where $\hat{H}_i (i = L, R)$ described the left (right) uncoupled quantum dots.

$$\hat{H}_L = \sum_{\sigma} \epsilon_{s\sigma} |s\sigma\rangle \langle s\sigma|$$

With

$$\epsilon_{s\sigma} = \epsilon_s + \Delta_{L,\sigma}$$

Where $\epsilon_s$ is the energy of the level $s$ in the left quantum dot.

$\Delta_i (i = L, R)$ is the Zeeman splitting in the states of the two dots and $\Delta_L \neq \Delta_R$ because of the different g-factor.

$$\Delta_{i,\sigma} = g_i \mu_B B \sigma$$

$g_i$ is the land g-factor, $\mu_B$ is the Bohr magneton, $\mu_B = e\hbar/2m$

$$\mu_B = 9.274 \times 10^{-21} \text{erg per Gauss per particlal}$$

$B$ is the applied DC magnetic field, and $\sigma$ is the spin operator $\sigma = +1$ for spin up and $\sigma = -1$ for spin down. We use for the value of the g-factor $g_L = -0.33$ and $g_R = -0.89^{(14)}$.

The second part of the Hamiltonian $\hat{H}_R$ can be described as;

$$\hat{H}_R = (E_B + \Delta_{R,\sigma})|1\sigma\rangle \langle 1\sigma| + \Delta_{R,\sigma}|2\sigma\rangle \langle 2\sigma| - (E_B - \Delta_{R,\sigma})|3\sigma\rangle \langle 3\sigma|$$

$$+ L_c (|1\sigma\rangle \langle 2\sigma| + |2\sigma\rangle \langle 1\sigma| + |2\sigma\rangle \langle 3\sigma| + |3\sigma\rangle \langle 2\sigma|)$$  \hspace{1cm} (2)
With $1\sigma$, $2\sigma$, and $3\sigma$ are the levels of the right quantum dot, $E_B = c_B(B - B_0)$ is the magnetic energy corresponding to the applied magnetic field, $c_B$ is a constant describes the magnetic field dependence of the Fock–Darwin (FD)\(^{(15)}\) orbitals and $L_c$ is the coupling between the nearest levels of the right quantum dot.

The Hamiltonian $\hat{H}_{LR}$ describe the interaction between the left and right quantum dots and is given by:

$$\hat{H}_{LR} = \sum_{\alpha, \sigma}(\gamma_{\alpha\sigma}|s\sigma\rangle\langle\Psi_{\alpha\sigma}| + \text{H.c.})$$

Where $\gamma_{\alpha\sigma}$ is the hopping rate of an electron between states $|s\sigma\rangle$ and $|\Psi_{\alpha\sigma}\rangle$.

And $\hat{H}_T$ in eq(1) represents the interaction between the double quantum dots (DQD) and the leads.

$$\hat{H}_T = \sum_{l \in \{L,R\}} \sum_{kj\sigma}(\gamma_{lk\sigma}|l\sigma\rangle\langle k\sigma| + \text{H.c.})$$

The Hamiltonian of the leads is described by:

$$\hat{H}_{\text{leads}} = \sum_{lk\sigma}\epsilon_{lk}|lk\sigma\rangle\langle lk\sigma|$$

$\epsilon_{lk}$ described two standard fermionic reservoirs, and $l = L/R$ lead.

**3. Energies and wave functions of right quantum dot**

In order to calculate the energy and the wave functions for the second dot; we use the Hamiltonian $\hat{H}_R$ in the Schrödinger equation

$$\hat{H}\Psi = \epsilon\Psi \quad (3)$$

We get

$$\epsilon_{0\sigma} = \Delta_{R,\sigma} \quad (4)$$

$$\epsilon_{\pm\sigma} = \pm \sqrt{E_B^2 + 2L_c^2 + \Delta_{R,\sigma}} \quad (5)$$
And the wave functions are corresponding to these eigen values are,

\[ |\Psi_0\rangle = \frac{1}{\sqrt{E_B^2 + 2L_c^2}}(-L_c|1\rangle + E_B|2\rangle + L_c|3\rangle) \]

\[ |\Psi_\pm\rangle = \frac{L_c^2}{E_B^2 + 2L_c^2 \pm E_B\sqrt{E_B^2 + 2L_c^2}}|1\rangle \pm \frac{L_c}{\sqrt{E_B^2 + 2L_c^2}}|2\rangle \]

\[ + \frac{L_c^2}{E_B^2 + 2L_c^2 \mp E_B\sqrt{E_B^2 + 2L_c^2}}|3\rangle \]  

(6)

The overlap between the state \( |s\sigma\rangle \) of the left QD and the states \( |\Psi_{\alpha\sigma}\rangle \) of the right QD can be calculated as:

\[ \langle s|\Psi_0 \rangle = \frac{-L_c}{\sqrt{E_B^2 + 2L_c^2}}\langle s|1\rangle \pm \frac{E_B}{\sqrt{E_B^2 + 2L_c^2}}\langle s|2\rangle \pm \frac{L_c}{\sqrt{E_B^2 + 2L_c^2}}\langle s|3\rangle \]

Where \( \langle s|i\rangle = s_i \), \( i = 1, 2, 3 \), \( |i\rangle \) are the Fock-Darwin wave functions.

This eigenstate-overlap clearly vanishes for \( E_B = T(s_1 - s_3)/s_2 \). One can assumed here that \( \langle s|i\rangle \) are the same for the all wave functions of the Fock-Darwin levels and for this reason we can set the square of the matrix elements as follow,

\[ \langle s|\Psi_0 \rangle = \frac{E_B}{\sqrt{E_B^2 + 2L_c^2}}s_2 \]

\[ \langle s|\Psi_\pm \rangle = s_1 \pm \frac{L_c}{\sqrt{E_B^2 + 2L_c^2}}s_2 \]

And the squares of the relevant matrix elements are:

\[ |\langle s|\Psi_0 \rangle|^2 = \frac{E_B^2}{E_B^2 + 2L_c^2} \]  

(7)

\[ |\langle s|\Psi_\pm \rangle|^2 = 1 \pm \frac{L_c^2}{E_B^2 + 2L_c^2} \pm \frac{2L_c}{\sqrt{E_B^2 + 2L_c^2}} \]  

(8)
4. Tunneling rate

The hopping rate of an electron between states $|s\sigma\rangle$ and $|\Psi_{a\sigma}\rangle$ can be calculated as

$$\gamma_{a\sigma} = \gamma |\langle s\sigma|\Psi_{a\sigma}\rangle|^2 \varrho(\epsilon_{s\sigma}, \epsilon_{a\sigma}; \Gamma_{\sigma})$$

(9)

$q(\epsilon_{s\sigma}, \epsilon_{a\sigma}; \Gamma_{\sigma})$ describes the broadening of the hybridization function of the dots levels at the density of states of leads,

$$q(\epsilon_{s\sigma}, \epsilon_{a\sigma}; \Gamma_{\sigma}) = \frac{\Gamma^2}{(\epsilon_{s\sigma} - \epsilon_{a\sigma})^2 + \Gamma^2}$$

and

$$\Gamma_{\sigma} \equiv \Gamma_{L,\sigma} + \Gamma_{R,\sigma}$$

$\Gamma_{L/R,\sigma} = \Gamma$ is the tunnelling rate of an electron with spin $\sigma$ between the dot and the left/right leads.

Figure 2 shows the hopping rates, $\gamma_{a\sigma}$ as a function of the applied magnetic field $B$, we represents here the case of a large $\epsilon_s$, which can be achieved by adjusting the gate voltage on the left QD. In this case, the large $\epsilon_s$ leads to s-orbit resonating close with the “+” channel, this transition shows that the large peaks for $\gamma_+$ in comparison with the other peaks for $\gamma_0$ and $\gamma_-$ comes from the resonance condition.

In this system, large $\epsilon_s$ is consider to leads to the s-orbit resonating close with + channel in the right quantum dot, large $\epsilon_s$ obtained by adjusting the gate voltage in the left quantum dot. There are two parameters affected the transport in this system, one is the spin-dependent energy level $\epsilon_{+\sigma}$ and the

Figure 2: The spin-dependent hopping rates $\gamma_{a\sigma}$ versus magnetic field $B_{dc}$. (a) $\gamma_{+\sigma}$, (b) $\gamma_{0\sigma}$ and (c) $\gamma_{-\sigma}$. Parameters used are $L_c = 1 \text{ meV}$, $\Gamma = 10 \mu\text{eV}$, $\gamma = 100 \mu\text{eV}$, $\epsilon_s = 1.5 \text{ meV}$, and $B_0 = 5.2 T$. 

other is the Dc-magnetic field that applied on the system.

From Fig(2), one can see that tunneling rate depend on the spin $\sigma$ also the peaks which appears in this figure is due to resonance tunneling when the s-orbit in the left quantum dot is aligned to the $\epsilon_{+\sigma}$ level in the right quantum dot.

In order to see the effects of the different parameters on the hopping rate, we take different values to the $\epsilon_s$ as shown in Fig. (3a) and (3b).

Fig.(3a) shows more brooding in the spin down rate when $\epsilon_s$ is less than 1.5 meV and when $\epsilon_s$ greater than 1.5 meV the spin down rate shows two peaks. The effect of the parameters $L_c$, which is responsible the coupling strength between the levels due to anisotropy of the right quantum dot, is shown in figure (4a) and (4b).

The change effect of the leads in the system can be achieved by changing the parameters $\Gamma$ which is defined the hybridization of the level of the right quantum dot with the density of state of the right lead, that is to say the rate between right quantum dot and the right lead as shown in the figure (5a), and (5b).

5. The basis states

The basis states in double quantum dots containing two electrons are distributed under the consideration of one electron is confined in the left dot and the other electron participating if transport process, so these bases are:

For one electron

$$|1\rangle = |\uparrow,0\rangle, |2\rangle = |\downarrow,0\rangle$$

And for two electrons

$$|3\rangle = |\uparrow\downarrow,0\rangle, |4\rangle = |\uparrow,\downarrow_0\rangle, |5\rangle = |\uparrow,\downarrow_0\rangle, |6\rangle = |\uparrow,\downarrow_0\rangle, |7\rangle = |\uparrow,\uparrow_+\rangle, |8\rangle = |\uparrow,\uparrow_0\rangle, |9\rangle = |\uparrow,\uparrow_-\rangle$$

$$|10\rangle = |\downarrow,\uparrow_+\rangle, |11\rangle = |\downarrow,\uparrow_0\rangle, |12\rangle = |\downarrow,\downarrow_-\rangle, |13\rangle = |\downarrow,\downarrow_0\rangle, |14\rangle = |\downarrow,\downarrow_0\rangle, |15\rangle = |\downarrow,\downarrow_-\rangle$$
Figure 3: The spin-dependent hopping rates $\gamma_{\alpha\sigma}$ versus magnetic field $B_{dc}$ for different values of $\epsilon_s$.

Figure 4: The spin-dependent hopping rates $\gamma_{\alpha\sigma}$ versus magnetic field $B_{dc}$ for different values of $L_c$.

Figure 5: The spin-dependent hopping rates $\gamma_{\alpha\sigma}$ versus magnetic field $B_{dc}$ for different values of $\Gamma$.
Equation of motion\(^{(16)}\) [16] can be used to described the dynamics of the double dots system

$$\dot{\rho}(t)_s = \sum_{m \neq s} W_{sm}\rho_m - \sum_{k \neq s} W_{ks}\rho_s$$

\(\rho\) is the state occupation probability

\(W_{ij}\) is the transition rate from state \(j\) to state \(i\) and it’s defined by different methods according to processes in the system such as

\(|\downarrow, 0\rangle \rightarrow |\uparrow\downarrow, 0\rangle \implies W_{3,2} = \Gamma_{L,\uparrow}\),

\(|\downarrow, \downarrow\rangle \rightarrow |\uparrow, \downarrow\rangle \implies W_{5,14} = \left[\frac{1}{T_{sf}}\right]_L\),

\(|\uparrow\downarrow, 0\rangle \rightarrow |\uparrow, \downarrow\rangle \implies W_{6,3} = \gamma - \downarrow\)

Where \(T_{sf}\) is the time for electron to reverse (flip) it’s spin. The other transition rates can be calculated in the same way. With the inclusion of the spin-flip interactions, the rate equations for the occupation probabilities of \(|2\rangle, |3\rangle, |4\rangle and |5\rangle\) are:

\[
\dot{\rho}_2 = W_{2,1}\rho_1 + W_{2,10}\rho_{10} + W_{2,11}\rho_{11} + W_{1,12}\rho_{12} + W_{1,13}\rho_{13} + W_{1,14}\rho_{14} + W_{1,15}\rho_{15} - W_{1,2}\rho_2 - W_{3,2}\rho_2
\]

\[
\dot{\rho}_3 = W_{3,1}\rho_1 + W_{3,2}\rho_2 + W_{3,4}\rho_4 + W_{3,5}\rho_5 + W_{3,6}\rho_6 + W_{3,10}\rho_{10} + W_{3,11}\rho_{11} + W_{3,12}\rho_{12} - W_{4,3}\rho_3 - W_{5,3}\rho_3 - W_{6,3}\rho_1 - W_{10,3}\rho_3 - W_{11,3}\rho_3 - W_{12,3}\rho_3
\]

\[
\dot{\rho}_4 = W_{4,3}\rho_3 + W_{4,7}\rho_7 + W_{4,13}\rho_{13} - W_{1,4}\rho_4 - W_{3,4}\rho_4 - W_{4,4}\rho_4 - W_{7,4}\rho_4 - W_{13,4}\rho_4
\]

\[
\dot{\rho}_5 = W_{5,3}\rho_3 + W_{5,8}\rho_8 + W_{5,14}\rho_{14} - W_{1,5}\rho_5 - W_{3,5}\rho_5 - W_{8,5}\rho_5 - W_{14,5}\rho_5
\]

For the steady state one can calculate every \(\rho_m\), \((m = 1, \ldots, 15)\) in the system.
6. Current calculation

We are mainly interested in the calculation of the current from the right dot to the right lead in the system, for different electron spin

\[ I_\uparrow = e \Gamma_{R\uparrow}(\rho_7 + \rho_8 + \rho_9 + \rho_{10} + \rho_{11} + \rho_{12}) \]

\[ I_\downarrow = e \Gamma_{R\downarrow}(\rho_4 + \rho_5 + \rho_6 + \rho_{13} + \rho_{14} + \rho_{15}) \]

The calculation under small spin-flip rates leads to an approximate formula for the current

\[ I_\uparrow = \Gamma \left( \frac{Y_{\uparrow\uparrow}\rho_3}{\Gamma + Y_{\uparrow\uparrow}} \right) \] \hspace{1cm} (10) \]

\[ I_\downarrow = \Gamma \left( \frac{Y_{\downarrow\downarrow}\rho_3}{\Gamma + Y_{\downarrow\downarrow}} \right) \] \hspace{1cm} (11) \]

And for the average total current is given by:

\[ \langle I \rangle = I_{\uparrow} + I_{\downarrow} \]

\[ \langle I \rangle = \frac{\Gamma^2(Y_{\uparrow\uparrow} + Y_{\downarrow\downarrow}) + 2\Gamma Y_{\uparrow\downarrow}Y_{\downarrow\uparrow}}{\Gamma^2 + \Gamma(Y_{\uparrow\uparrow} + Y_{\downarrow\downarrow}) + Y_{\uparrow\downarrow}Y_{\downarrow\uparrow}} \] \hspace{1cm} (12) \]

The relation between the current and the static magnetic field for spin up is shown in figure (6a), the current shows two peaks because its depends on the a magnetic field with a complicated relation and the maximum of these peaks are related to the resonance energy of the level \( \epsilon_{s\uparrow} \) and the level \( \epsilon_{+\uparrow} \) in the right quantum dot.

Figure (6b) show the spin down current which has a peak around \( B_0 \), the average total current is listed in figure (6c) for the same parameters values of \( \epsilon_s, L_c \) and \( \gamma \). From figure (6) no spin blockade are observed.

Figure 6: Current \( I \) versus magnetic field \( B \). (a) \( I_{\uparrow\uparrow} \), (b) \( I_{\downarrow\downarrow} \) and (c) \( I_{\uparrow\uparrow} + I_{\downarrow\downarrow} \)
